

Abstract:

To create a sense of optical depth when a display device is observed, the invention provides a display device (1) having
5 a luminous element and a laterally structured luminous surface having at least one region that is capable of illumination, as well as at least two light-reflecting layers (7, 9) which are spaced apart from one another and between which light emitted by the luminous surface is reflected back
10 and forth, at least one of the light-reflecting layers (7, 9) being semitransparent, and at least one of the light-reflecting layers (7, 9) being arranged at a distance from the luminous element.
